#### Abstract

In the present day, a significant portion of the world's energy demand can be satisfied through the utilization of renewable energy sources. Solar energy, in particular, holds a pivotal position owing to its numerous merits. However, it faces a challenge known as mismatch response within the photovoltaic (PV) modules of an array when subjected to partial shading. This issue restricts power output, leads to the formation of local hot spots, and results in the underutilization of PV modules within the array. One of the most effective solutions to address this problem is optimizing the PV array (PVA) configuration to maximize output power under partial shading (PS) conditions. In this research paper, we commence with a thorough numerical analysis under uniform shading conditions. Following that, we scrutinize the performance of six traditional PVA configurations and three hybrid PVA configurations under PS conditions. The results consistently indicate that the Total Cross Tied (TCT) configuration outperforms others in all shading scenarios in terms of mitigating mismatch power loss, enhancing the fill factor, and improving overall efficiency.

## 1. INTRODUCTION

Energy is absolutely necessary for the expansion and prosperity of the economy. Because of the swift acceleration of industrialization and the push toward economic expansion, the world has a massive demand for power (Husain 2018). These days, consumers around the world are demanding uninterrupted power supply. Many factors such as lack of fuel, load shedding, internal failures, and many other factors can cause disruption in a conventional electrical system. Therefore, the integration of renewable resources has become more popular, and their functions are to meet global demand (Krishna 2019). Among several renewable resources, solar energy gains greater importance because of its merits like abundance, ecofriendliness, and also advancements in semiconductor technology (Tatabhatla 2019). In spite of these merits, solar systems suffer from low efficiency, large susceptance to environmental changes, partial shading, and dust deposition, which leads to a reduction in the output power of the solar system. Among these, partial shading creates a huge impact on the system's efficiency. The key factors that contribute to partial shade conditions include tree shadows, towers and other structures, moving clouds, aging-related cell damage, bird droppings, and soiling (Harish Kumar Varma 2021). In order to get the correct voltage and current as required by the load, a large number of modules are connected in series and parallel to form the PV arrays. The electrical characteristics of shaded and unshaded panels differ under shading conditions, and this characteristic discrepancy increases as the illumination intensities change. The mismatching causes a drastic drop in
output power under real-world operating conditions. The amount of power lost due to shading depends on a number of variables, including the intensity of shading, where in the PV array the shaded panels are located, and, most crucially, the arrangement of the PV panels themselves.

Over the years, many partial shade mitigation strategies have been developed in order to extend the lifetime of PV modules as well as to maximize the amount of energy that can be harvested from solar PV modules. Despite having poor efficiency, these methods have allowed the PV system to be employed in systems for water pumping, commercial and residential buildings, electric vehicles, etc. There are primarily two categories for partial shade mitigation, which are 1) passive mitigation solutions, such as bypass diodes and PV array topologies, and 2) active mitigation methods, such as multilevel inverters, distributed MPPT approaches, and static and dynamic reconfiguration strategies. (i) According to the literature, the partial shading effects can be mitigated by: (i) Connection of bypass diodes (Bhadoria 2020) - which mitigates the formation of local hot spots but results in the formation of many peak power points on the I-V and P-V characteristics. Because of this, conventional maximum power point tracking (also known as MPPT) does not successfully track the global peak value. (ii) Usage of Global maximum power tracking techniques (Goud 2018) - Because of this, the total number of sensors in the system must be increased, as

[^0]
must the cost of these sensors. Furthermore, this raises the computational difficulty and memory necessity. (iii) Distributed MPPT converter system (Zhou 2020) - Each PV module's power electronic converters with MPPT allow it to function at maximum power. However, the high number of converters needed raises the overall system price. (iv) Implementing PV array configuration scheme (Kho 2018) - In (F. Belhachat 2015), Comprehensive research on S, P, SP, TCT, BL , and HC topologies has been presented by the authors. Under conditions of partial shading, the authors found that the results unequivocally demonstrate that the performances of the various PV array configurations are variable and strongly depend on the intensity of shading, the shading pattern, the location of the shading pattern, and the type of shading that is affecting the PV array. It is concluded in (Okan Bingol 2018) that the T-C-T PV array topology generates the maximum power by mitigating the mismatching power losses due to a smaller number of series interconnections compared with $\mathrm{S}, \mathrm{P}$, S-P, T-C-T, B-L, and H-C topologies under uniform and various shading patterns like uneven row, uneven column, diagonal, and random shading patterns. The authors of (Prem kumar 2020) discussed the performance of the conventional and hybrid topologies and came to the conclusion that the TCT configuration was superior to the other topologies in terms of delivering the highest output power. In this paper, Conventional and Hybrid configurations are analyzed using a $6 \times 6 \mathrm{PV}$ array using the SunPower SPR-76R-BLK-U PV module, and specifications are mentioned in Table - 1. The main objective of this research work is,

- Mathematical representation of conventional and hybrid topologies in partial shading.
- Analyze conventional and hybrid topologies by shading factor, operating panels, array voltage, array current, and array power at each string voltage interval.
- Economic study of conventional and hybrid topologies.

This paper is arranged as follows: Section 2 analyzes TCT PV Array Configurations under uniform shading condition. Section 3 represents the numerical analysis of PVA configuration under different shading conditions. Section 4 compares conventional and hybrid PV array configurations for different shading conditions, including performance and economic analysis. Finally, section 5 ends with a conclusion.

Table 1. Specifications of SunPower SPR-76R-BLK-U PV module

| S. no | Specifications | Values |
| :---: | :---: | :---: |
| 1 | Peak Power $\left(\mathrm{P}_{\mathrm{Pe}}\right)$ | $76.275(\mathrm{~W})$ |
| 2 | Open circuit voltage $\left(\mathrm{V}_{\mathrm{OC}}\right)$ | $16.2(\mathrm{~V})$ |
| 3 | Short-circuit current $\left(\mathrm{I}_{\mathrm{SC}}\right)$ | $6.02(\mathrm{~A})$ |
| 4 | Peak power point voltage $\left(\mathrm{V}_{\mathrm{pe}}\right)$ | $13.5(\mathrm{~V})$ |
| 5 | Peak power point current $\left(\mathrm{I}_{\mathrm{pe}}\right)$ | $5.65(\mathrm{~A})$ |
| 6 | Module area $(\mathrm{A})$ | $0.54\left(\mathrm{~m}^{2}\right)$ |

(e) Long Wide (LW)

Figure 2. Shading Patterns
In this work, six conventional PVA configurations such as Series Parallel (SP), Total Cross Tied (TCT), Bridge Link (BL), Honey Comb (HC), Ladder (LD), Triple Cross Tied (TrCT) and three hybrid PVA configurations such as Series Parallel - Total Cross Tied (SPTCT), Bridge Link - Total Cross Tied (BLTCT), Honey Comb - Total Cross Tied (HCTCT) configurations are considered, as shown in Fig 1. The mentioned PVA configurations are analyzed under diagonal (DIA), short narrow (SN), short wide (SW), long narrow (LN) and long wide (LW) shading conditions, as shown in Fig 2.

### 2.1 Numerical representation of TCT Configurations under uniform shading

The equivalent photo current under the unshaded condition, $\mathrm{I}_{\text {USH }}$ is expressed as
$\mathrm{I}_{\mathrm{USH}}=\mathrm{I}_{\mathrm{L}} \times \frac{\mathrm{G}}{\mathrm{G}_{\mathrm{STC}}} \approx \mathrm{I}_{\mathrm{SC}} \times \frac{\mathrm{G}}{\mathrm{G}_{\mathrm{STC}}}$
where $\mathrm{I}_{\mathrm{L}}, \mathrm{G}_{\text {STC }}$ : Photo current and Irradiance in Standard Test Conditions (STC) \& $\mathrm{G}_{\text {STC }}=1000 \mathrm{~W} / \mathrm{m}^{2}$; G: Irradiance falling on the module under shading condition, $\mathrm{I}_{\mathrm{SC}}$ : Short circuit current of the PV Module.

The equivalent photo current under the shaded condition , $\mathrm{I}_{\mathrm{SH}}$ is expressed as

$$
\begin{equation*}
I_{S H}=I_{L} \times \frac{G_{S H}}{G_{S T C}}=I_{L} \times \frac{(1-\beta) G}{G_{S T C}}=I_{U S H}-\left(\frac{G \times \beta}{G_{S T C}} \times I_{L}\right) \tag{2}
\end{equation*}
$$

where $\beta$ : Shading factor and it is expressed as $\beta=1-\frac{G_{S H}}{G}$ and $\mathrm{G}_{\mathrm{SH}}$ : Irradiance on shading condition

### 2.1.1 TCT configuration under the Diagonal (DIA) shading condition:

As can be seen in Figure 3, diagonal modules, i.e., $1,8,15,22,29$ and 36 , are under the shading condition and it is assumed that shading intensity is $600 \mathrm{~W} / \mathrm{m}^{2}$, meaning that $\beta=$ 0.4.

Figure 3. TCT configuration under diagonal shading
From the equivalent circuit of PV module (S.R.Pendem 2018), (AA. Desai 2021) the unshaded module current $\left(\mathrm{I}_{\mathrm{A}}\right)$ and shaded module current $\left(\mathrm{I}_{\mathrm{B}}\right)$ are expressed as
$I_{A}=I_{U S H}-I_{o}\left[\exp \left(\frac{q \times V_{U S H}}{n K T}\right)-1\right]$
Where (V, I) ush $=$ Voltage \& Currents of the Unshaded modules $=(\mathrm{V}, \mathrm{I})_{2-6,7,9-12, ~ 13,14, ~ 16-18, ~ 19-21, ~ 23,24, ~ 25-28,30, ~ 31-~}^{\text {- }}$ 35
(4)

Similarly:
$I_{B}=I_{S H}-I_{o}\left[\exp \left(\frac{q \times V_{S H}}{n K T}\right)-1\right]$
Where (V, I) SH $\quad=$ Voltage \& Currents of the Shaded modules $=(\mathrm{V}, \mathrm{I})_{1,8,15,22,29,36}(6)$

From Fig (4), the array current $\left(\mathrm{I}_{\mathrm{Te}}\right)$ is expressed as:
$\mathrm{I}_{\mathrm{Te}}=\mathrm{I}_{\mathrm{s} 1}+\mathrm{I}_{\mathrm{s} 2}+\mathrm{I}_{\mathrm{s} 3}+\mathrm{I}_{\mathrm{s} 4}+\mathrm{I}_{\mathrm{s} 5}+\mathrm{I}_{\mathrm{s} 6}$
where
$\mathrm{I}_{\mathrm{s} 1}=\mathrm{I}_{1}=\mathrm{I}_{2}=\mathrm{I}_{3}=\mathrm{I}_{4}=\mathrm{I}_{5}=\mathrm{I}_{6} ; \mathrm{I}_{\mathrm{s} 2}=\mathrm{I}_{7}=\mathrm{I}_{8}=\mathrm{I}_{9}=$
$\mathrm{I}_{10}=\mathrm{I}_{11}=\mathrm{I}_{12} ; \mathrm{I}_{\mathrm{s} 3}=\mathrm{I}_{13}=\mathrm{I}_{14}=\mathrm{I}_{15}=\mathrm{I}_{16}=\mathrm{I}_{17}=\mathrm{I}_{18}$
$; \mathrm{I}_{\mathrm{s} 4}=\mathrm{I}_{19}=\mathrm{I}_{20}=\mathrm{I}_{21}=\mathrm{I}_{22}=\mathrm{I}_{23}=\mathrm{I}_{24} ; \mathrm{I}_{\mathrm{s} 5}=\mathrm{I}_{25}=$
$\mathrm{I}_{26}=\mathrm{I}_{27}=\mathrm{I}_{28}=\mathrm{I}_{29}=\mathrm{I}_{30} ; \mathrm{I}_{56}=\mathrm{I}_{31}=\mathrm{I}_{32}=\mathrm{I}_{33}=$
$\mathrm{I}_{34}=\mathrm{I}_{35}=\mathrm{I}_{36}$
and the row voltages can be expressed as,
$\mathrm{V}_{\mathrm{R} 1}=\mathrm{V}_{1}=\mathrm{V}_{7}=\mathrm{V}_{13}=\mathrm{V}_{19}=\mathrm{V}_{25}=\mathrm{V}_{31} ; \mathrm{V}_{\mathrm{R} 2}=\mathrm{V}_{2}=$
$\mathrm{V}_{8}=\mathrm{V}_{14}=\mathrm{V}_{20}=\mathrm{V}_{26}=\mathrm{V}_{32} ; \mathrm{V}_{\mathrm{R} 3}=\mathrm{V}_{3}=\mathrm{V}_{9}=\mathrm{V}_{15}=$
$\mathrm{V}_{21}=\mathrm{V}_{27}=\mathrm{V}_{33} ; \mathrm{V}_{\mathrm{R} 4}=\mathrm{V}_{4}=\mathrm{V}_{10}=\mathrm{V}_{16}=\mathrm{V}_{22}=\mathrm{V}_{28}=$
$\mathrm{V}_{34} ; \mathrm{V}_{\mathrm{R} 5}=\mathrm{V}_{5}=\mathrm{V}_{11}=\mathrm{V}_{17}=\mathrm{V}_{23}=\mathrm{V}_{29}=\mathrm{V}_{35}$;
$V_{\mathrm{R} 6}=\mathrm{V}_{6}=\mathrm{V}_{12}=\mathrm{V}_{18}=\mathrm{V}_{24}=\mathrm{V}_{30}=\mathrm{V}_{36}$

From Eq. (7) and Eq. (8),
$\mathrm{I}_{\mathrm{Te}}=\mathrm{I}_{1}+\mathrm{I}_{7}+\mathrm{I}_{13}+\mathrm{I}_{19}+\mathrm{I}_{25}+\mathrm{I}_{31}=\mathrm{I}_{\mathrm{B}}+5 \mathrm{I}_{\mathrm{A}}$
$=\mathrm{I}_{\mathrm{SH}}-\mathrm{I}_{\mathrm{o}}\left[\exp \left(\frac{\mathrm{q} \times \mathrm{V}_{1}}{\mathrm{nKT}}\right)-1\right]+\mathrm{I}_{\mathrm{USH}}-$
$\mathrm{I}_{\mathrm{o}}\left[\exp \left(\frac{\mathrm{q} \times \mathrm{V}_{7,13,19,25,31}}{\mathrm{nKT}}\right)-1\right]$
$=I_{U S H}-\left(\frac{G \times \beta}{G_{\text {STC }}} \times I_{L}\right)-I_{o}\left[\exp \left(\frac{q \times V_{1}}{n K T}\right)-1\right]+I_{L} \times \frac{G}{G_{S T C}}$
$-I_{o}\left[\exp \left(\frac{q \times V_{7,13,19,25,31}}{\mathrm{nKT}}\right)-1\right]$
From Eq. (9) and Eq. (11), the modified ( $\mathrm{I}_{\mathrm{Te}}$ ) is given as
$=6 \mathrm{I}_{\mathrm{L}}\left(\frac{\mathrm{G}}{\mathrm{G}_{\text {STC }}}\right)-\left(\frac{\mathrm{G} \times \beta}{\mathrm{G}_{\text {STC }}} \times \mathrm{I}_{\mathrm{L}}\right)-6 \mathrm{I}_{\mathrm{o}}\left[\exp \left(\frac{\mathrm{q} \times \mathrm{V}_{1}}{\mathrm{nKT}}\right)-1\right]$
Similarly
$\mathrm{V}_{1}=\mathrm{V}_{2}=\mathrm{V}_{3}=\mathrm{V}_{4}=\mathrm{V}_{5}=\mathrm{V}_{6}=$
$\frac{\mathrm{nKT}}{\mathrm{q}} \times \ln \left[\frac{6 \mathrm{I}_{\mathrm{L}}\left(\frac{\mathrm{G}}{\mathrm{G}_{\mathrm{STC}}}\right)-\left(\frac{\mathrm{G} \times \beta}{\mathrm{G}_{\mathrm{STC}}} \times \mathrm{I}_{\mathrm{L}}\right)-\mathrm{I}_{\mathrm{Te}}}{6 \mathrm{I}_{\mathrm{O}}}+1\right]$

### 2.1.2 TCT configuration under Short Narrow (SN) shading condition:

Figure 4. TCT configuration under Short Narrow (SN) shading

Based on the shading condition shown in Figure 4, the total array current can be divided into unshaded row current $\left(\mathrm{I}_{\mathrm{Te}}\right)_{\text {ush }}$ and shaded row current $\left(I_{T e}\right)_{\text {sh }}$.
$\mathrm{I}_{\text {Te, ush }}=\mathrm{I}_{1}+\mathrm{I}_{7}+\mathrm{I}_{13}+\mathrm{I}_{19}+\mathrm{I}_{25}+\mathrm{I}_{31}=\mathrm{I}_{\text {USH }}-$ $\mathrm{I}_{\mathrm{o}}\left[\exp \left(\frac{\mathrm{q} \times \mathrm{V}_{1}}{\mathrm{nKT}}\right)-1\right]$
and $\quad \mathrm{I}_{\text {Te,sh }}=\mathrm{I}_{5}+\mathrm{I}_{11}+\mathrm{I}_{17}+\mathrm{I}_{23}+\mathrm{I}_{29}+\mathrm{I}_{35}$
$=I_{U S H}-\left(\frac{G \times \beta}{G_{S T C}} \times I_{L}\right) \quad-I_{o}\left[\exp \left(\frac{q \times V_{5}}{n K T}\right)-1\right]+I_{U S H}-$ $\left(\frac{\mathrm{G} \times \beta}{\mathrm{G}_{\text {STC }}} \times \mathrm{I}_{\mathrm{L}}\right)-\mathrm{I}_{\mathrm{O}}\left[\exp \left(\frac{\mathrm{q} \times \mathrm{V}_{11}}{\mathrm{nKT}}\right)-1\right]+\mathrm{I}_{\text {USH }}-\left(\frac{\mathrm{G} \times \beta}{\mathrm{G}_{\text {STC }}} \times \mathrm{I}_{\mathrm{L}}\right)$
$-I_{o}\left[\exp \left(\frac{q \times V_{17}}{n K T}\right)-1\right]+I_{U S H}-\left(\frac{G \times \beta}{G_{S T C}} \times I_{L}\right)$
$-I_{0}\left[\exp \left(\frac{q \times V_{23}}{n K T}\right)-1\right]+I_{U S H}-\left(\frac{G \times \beta}{G_{\text {STC }}} \times I_{L}\right)$
$-I_{o}\left[\exp \left(\frac{q \times V_{29}}{n K T}\right)-1\right]+I_{U S H}-\left(\frac{G \times \beta}{G_{S T C}} \times I_{L}\right)$
$-I_{o}\left[\exp \left(\frac{q \times V_{35}}{n K T}\right)-1\right]$
From Eq. (9), $\mathrm{I}_{\mathrm{Te}, \text { sh }}$ can be rewritten as
$\mathrm{I}_{\mathrm{Te}, \text { sh }}=6 \mathrm{I}_{\mathrm{USH}}-\left(\frac{2 \mathrm{G} \times \beta}{\mathrm{G}_{\text {STC }}} \times \mathrm{I}_{\mathrm{L}}\right)-6 \mathrm{I}_{\mathrm{o}}\left[\exp \left(\frac{\mathrm{q} \times \mathrm{V}_{5}}{\mathrm{nKT}}\right)-1\right]$
Similarly, from Eq. (14) and Eq. (15), we have:
$\mathrm{V}_{1}=\mathrm{V}_{2}=\mathrm{V}_{3}=\mathrm{V}_{4}=\frac{\mathrm{nKT}}{\mathrm{q}} \times \ln \left[\frac{6 \mathrm{I}_{\mathrm{L}}\left(\frac{\mathrm{G}}{\mathrm{G}_{\mathrm{STC}}}\right)-\mathrm{I}_{\mathrm{Te}, \mathrm{ush}}}{6 \mathrm{I}_{\mathrm{o}}}+1\right]$
$\mathrm{V}_{5}=\mathrm{V}_{6}=\frac{\mathrm{nKT}}{\mathrm{q}} \times \ln \left[\frac{6 \mathrm{I}_{\mathrm{USH}}-\left(\frac{2 \mathrm{G} \times \beta}{\mathrm{G}_{\mathrm{GTC}}} \times \mathrm{I}_{\mathrm{L}}\right)-\mathrm{I}_{\mathrm{Te}, \mathrm{Sh}}}{6 \mathrm{I}_{\mathrm{O}}}+1\right]$
From Eqs. $(12,13)$ and Eqs. $(15-17)$, the short circuit current $\left(\mathrm{I}_{\mathrm{sc}}\right)$ and the point at which I-V curve changes its path $\left(\mathrm{I}_{\mathrm{cp}}\right)$, number of maximum values for $\beta=0.4$ and $G=1000 \mathrm{~W} / \mathrm{m}^{2}$ are mentioned in Table 2 and simulated results are shown in Figure 5. In addition, the same analysis is extended for the remaining shading patterns.

Table 2. Numerical analysis results of TCT configuration in the uniform shading condition

| Topology | Shading <br> Pattern | $\mathbf{I}_{\text {sc }}(\mathbf{A )}$ | $\mathbf{I}_{\mathbf{c p}}(\mathbf{A})$ | Maximum <br> Values |
| :---: | :---: | :---: | :---: | :---: |

|  | LW | $6 \mathrm{I}_{\mathrm{sc}}$ | $6 \mathrm{I}_{\mathrm{sc}}-4 \beta \mathrm{I}_{\mathrm{sc}}$ | 2 |

## 3. NUMERICAL ANALYSIS OF PV ARRAY CONFIGURATIONS UNDER PARTIAL SHADING CONDITONS

6 x 6 PVA topologies are simulated in the MATLAB/Simulink software under 5 partial shade situations, and numerical analysis is conducted in terms of the working modules, peak voltage ( $\mathrm{V}_{\mathrm{pe}}$ ), peak current ( $\mathrm{I}_{\mathrm{pe}}$ ), and peak power $\left(\mathrm{P}_{\mathrm{pe}}\right)$ as mentioned in Table [3-11].

### 3.1 Series-Parallel (SP) Configuration:

This configuration aims to balance the benefits of both series and parallel connections. The array is divided into smaller sub-arrays connected in parallel, with each sub-array having multiple modules connected in series. This configuration reduces the impact of shading on the entire array. If one sub-array is shaded, only that sub-array's performance is significantly affected, while other sub-arrays continue to operate at a higher efficiency. This allows the unaffected subarrays to contribute more to the overall power output, reducing the performance loss caused by shading. The MATLAB simulation connection is shown in Figure 6, and the simulated $\mathrm{I}-\mathrm{V}$ and $\mathrm{P}-\mathrm{V}$ curves are presented in Figure 7.

Figure 7. (a) Output Power - Voltage Curve (b) Output Current - Voltage Curve of SP Configuration

The number of local peaks generated is $1,2,2,4$, and 2 under DIA, SN, SW, LN, and LW shading conditions, respectively, and the global peak of $30 \mathrm{~V}_{\mathrm{pe}} \mathrm{I}_{\mathrm{pe}}$ is produced by the SP configuration under diagonal shading conditions, as mentioned in Table 3.

### 3.2 Total Cross Tied (TCT) PV array configuration:

The Total Cross Tied (TCT) PV array configuration, also known as Full Cross Tied or Fully Cross Tied, is a layout design
used in photovoltaic (PV) systems. In a TCT configuration, each module is connected in both series and parallel to its neighboring modules. In a TCT configuration, each module has multiple parallel paths, and bypass diodes are often strategically placed within each module to allow current to flow around shaded modules. This helps prevent the shaded module from significantly affecting the entire string's performance. The MATLAB simulation connection is shown in Figure 8, and the simulated I-V and P-V curves are presented in Figure 9.

Figure 9. (a) Output Power - Voltage Curve; (b) Output - Voltage Curve of TCT Configuration

The number of local peaks generated is $1,2,2,4$, and 2 under DIA, SN, SW, LN, and LW shading conditions, respectively, and the global peak of $30 \mathrm{~V}_{\mathrm{pe}} \mathrm{I}_{\mathrm{pe}}$ is produced by the SP configuration under diagonal shading conditions, as mentioned in Table 3.

### 3.3 Bridge - Link (BL) PV Array Configuration

The Total Cross Tied (TCT) PV array configuration, also known as Full Cross Tied or Fully Cross Tied, is a layout design used in photovoltaic (PV) systems. In a TCT configuration, each module is connected in both series and parallel to its
neighboring modules. In a TCT configuration, each module has multiple parallel paths, and bypass diodes are often strategically placed within each module to allow current to flow around shaded modules. This helps prevent the shaded module from significantly affecting the entire string's performance. The MATLAB simulation connection is shown in Figure 8, and the simulated I-V and P-V curves are presented in Figure 9.

The number of local peaks generated is $1,2,2,4$, and 2 under DIA, SN, SW, LN, and LW shading conditions, respectively, with a global peak of $30 \mathrm{~V}_{\mathrm{pe}} \mathrm{I}_{\mathrm{pe}}$ produced by the BL configuration under diagonal shading conditions, as mentioned in Table 5.

### 3.4 Honey Comb (HC) PV Array Configuration

The drawbacks associated with Series-Parallel (SP) PV array configurations can be mitigated by adopting an arrangement that resembles the hexagonal pattern found in honeycomb architecture. This arrangement demonstrates improved performance in situations with uneven array sizes or when the number of module rows is fewer than the parallel strings receiving the same irradiance. The honeycomb (HC) configuration features a greater number of series-connected modules per string compared to TCT and BL arrangements while presenting a lesser number of series-connected modules per string in comparison to the SP configuration. Consequently, this results in a comparatively higher power loss due to mismatches than observed in TCT and BL configurations, but the extent of this loss is comparatively lower when compared to the SP configuration. The MATLAB simulation connection is shown in Figure 12, and the simulated I-V and P-V curves are presented in Figure 13.

The number of local peaks generated is $4,2,2,4$, and 2 under DIA, SN, SW, LN, and LW shading conditions, respectively, with the global peak of 28 VpeIpe produced by the HC configuration under short and narrow shading conditions, as mentioned in Table 6.

### 3.5 Ladder (LD) PV Array Configuration

The PV modules within the first three columns of each row are linked together in a parallel arrangement. Subsequently, the rows themselves are connected in a series configuration. The MATLAB simulation connection and the simulated I-V and PV curves are shown in Figs. 14 and 15.

The number of local peaks generated is $3,2,2,4$, and 2 under DIA, SN, SW, LN, and LW shading conditions, respectively, with the global peak of 29.4 VpeIpe produced by the LD configuration under the diagonal shading condition, as mentioned in Table 7.

### 3.6 Triple Cross Tied (TrCT) PV Array Configuration

The arrangement of interconnection in the TrCT configuration draws inspiration from the structure of staircase flights and represents a modified version of the BL or HC configurations. In this arrangement, a sequence of three modules is interconnected, followed by a subsequent gap. Additionally, it can be interpreted as a cross-tie configuration due to the inclusion of cross ties that establish connections among the parallel strings. The MATLAB simulation connection is shown in Figure 16, and the simulated I-V and PV curves are presented in Figure 17.

The number of local peaks generated is $5,2,2,4$, and 2 under DIA, SN, SW, LN, and LW shading conditions, respectively, with the global peak of 31.8 VpeIpe produced by the TrCT configuration under diagonal shading condition, as mentioned in Table 8.

### 3.7 Series Parallel - Total Cross Tied (SPTCT) PV Array Configuration

The SPTCT arrangement is formulated by integrating the SP and T-C-T configurations in series. Consequently, a uniform current traverses both the SP and TCT configurations. Notably, the S-P-T-C-T topology exhibits enhanced performance compared to the SP, BL, and HC topologies across a wide spectrum of shading scenarios. The connection scheme for MATLAB simulations is presented in Figure 18, and the corresponding simulated $\mathrm{I}-\mathrm{V}$ and $\mathrm{P}-\mathrm{V}$ curves are shown in Figure 19.

The number of local peaks generated is $4,2,2,4$ and 2 under DIA, SN, SW, LN, and LW shading conditions, respectively, with the global peak of 28.8 VpeIpe produced by the SPTCT configuration under short and narrow shading conditions, as mentioned in Table 9.

Figure 19. (a) Output Power - Voltage Curve (b) Output Current - Voltage Curve of SPTCT Configuration

### 3.8 Bridge Link - Total Cross Tied (BLTCT) PV Array Configuration

This configuration is structured by establishing a series connection between the B-L and T-C-T topologies, ensuring a uniform current distribution across both the B-L and T-C-T configurations. Notably, the B-L-T-C-T topology excels in performance compared to the S-P, B-L, and H-C topologies. The connection scheme for MATLAB simulations is presented in Figure 20, and the corresponding simulated I-V and P-V curves are shown in Figure 21.

The number of local peaks generated is 5,2,2, 4 and 2 under DIA, SN, SW, LN, and LW shading conditions, respectively, with the global peak of 31.8 VpeIpe produced by the BLTCT configuration under diagonal shading conditions, as mentioned in Table 10.

### 3.9 Honey Comb - Total Cross Tied (HCTCT) PV Array Configuration

This configuration is structured by establishing a series connection between the $\mathrm{H}-\mathrm{C}$ and T-C-T topologies, ensuring a uniform current distribution across both the $\mathrm{H}-\mathrm{C}$ and $\mathrm{T}-\mathrm{C}-\mathrm{T}$ configurations. Notably, the H-C-T-C-T topology excels in performance compared to the S-P, B-L, and T-C-T topologies. The connection scheme for MATLAB simulations is presented in Figure 22, and the corresponding simulated I-V and P-V curves are shown in Figure 23.

The number of local peaks generated is $5,2,2,4$, and 2 under DIA, SN, SW, LN, and LW shading conditions, respectively, with the global peak of 31.8 VpeIpe produced by the BLTCT configuration under diagonal shading conditions, as mentioned in Table 11.

## 4. RESULTS AND DISCUSSION

This section outlines the results derived from assessing both conventional and hybrid photovoltaic (PV) array topologies across diverse shading patterns elaborated upon in Section 3. The parameters provided in reference (Suresh 2022) are employed to assess the performance of all PV arrangements across varying shading conditions, as indicated in Tables 12 and 13, and comparative assessment is shown in Figure 23.

### 4.1 Under No Shading Condition

Each PV module within the array configurations is exposed to solar irradiance of $1000 \mathrm{~W} / \mathrm{m} 2$. Under this shading scenario, both the conventional and proposed hybrid topologies operate
at Voc and Isc values of 97.2 V and 36.14 A , respectively. A singular peak at 2746 W is observed in the $\mathrm{P}-\mathrm{V}$ characteristics with the corresponding values for voltage (Vpe) and current (Ipe) are 81 V and 33.87 A and the $\mathrm{FF} \& \eta$ are 0.782 and $14.12 \%$, respectively.

### 4.2 Under Diagonal (DIA) Shading Condition

The TCT configuration produces the highest global peak power of 2490 W . The associated values for voltage (Vpe) and current (Ipe) are 84.7 V and 28.3 A , respectively. Comparatively, the SP, BL, HC, LD, TrCT, SPTCT, BLTCT, and HCTCT arrangements result in $1,1,4,3,5,4,5$, and 5 local peaks, respectively. For the TCT arrangement, PL, $\eta$, and fill factor (FF) are $1.88 \%, 13.84 \%$, and 0.68 , as specified in Table 13.

### 4.3 Under Short Narrow (SN) Shading Condition

The TCT configuration produces the highest global peak power of 2296 W . The associated values for voltage (Vpe) and current (Ipe) are 84.5 V and 27.17 A , respectively. Comparatively, the SP, BL, HC, LD, TrCT, SPTCT, BLTCT, and HCTCT arrangements result in 2 local peaks, respectively. For the TCT arrangement, the PL, $\eta$, and fill factor (FF) are $11.42 \%, 12.57 \%$, and 0.68 , as specified in Table 13.

### 4.4 Under Short Wide (SW) Shading Condition

The TCT configuration produces the highest global peak power of 1828 W . The associated values for voltage (Vpe) and current (Ipe) are 86.1 V and 21.23 A , respectively. Comparatively, the SP, BL, HC, LD, TrCT, SPTCT, BLTCT, and HCTCT arrangements result in 2 local peaks, respectively. For the TCT arrangement, the PL, $\eta$, and fill factor (FF) are $24.15 \%, 10.74 \%$, and 0.54 , as specified in Table 13.

### 4.5 Under Long Narrow (LN) Shading Condition

The TCT configuration produces the highest global peak power of 2224 W . The associated values for voltage (Vpe) and current (Ipe) are 84 V and 26.45 A , respectively. Comparatively, the SP, BL, HC, LD, TrCT, SPTCT, BLTCT, and HCTCT arrangements result in 4 local peaks respectively. For the TCT arrangement, the PL, $\eta$, and fill factor (FF) are $9.89 \%, 12.79 \%$, and 0.65 , as specified in Table 13.

### 4.6 Under Long Wide (LW) Shading Condition

The TCT configuration produces the highest global peak power of 1687 W . The associated values for voltage (Vpe) and
current (Ipe) are 85 V and 19.85 A , respectively. Comparatively, the SP, BL, HC, LD, TrCT, SPTCT, BLTCT, and HCTCT arrangements result in 2 local peaks, respectively.

For the TCT arrangement, PL, $\eta$, and fill factor (FF) are 22.97 $\%, 11.57 \%$, and 0.49 , as specified in Table 13.

Table 12 Global Powers, local Powers, Open circuit voltage and short circuit current of Conventional and Hybrid PV configurations

| Topology | Voc (V) | Isc (A) | Global Values |  |  | Local Values |  |  |

Figure 23. Comparative representation of conventional and hybrid configurations: (a) diagonal, (b) short narrow, (c) short wide, (d) long narrow, and (e) long wide

### 4.1 Payback time assessment of TCT configuration for Long Narrow (LN) Shading Condition:

The generated power in TCT $=2224 \mathrm{~W}$
The generated power in $\mathrm{SP}=2092 \mathrm{~W}$
$\%$ Power gain $=\frac{\left.\left(\left(\mathrm{P}_{\max }\right)_{\mathrm{TCT}}-\left(\mathrm{P}_{\max }\right) \mathrm{SP}\right)\right)}{\left(\mathrm{P}_{\max }\right) \mathrm{SP}} \times 100=6.3 \%$.
In a day, assuming a duration of partial shading $=4$ hours, then Power saving per day $=(2224-2092) * 4=0.528 \mathrm{kWh}$.

Then, the total units saved per annum $\approx 192.72 \mathrm{kWh}=193$ units.

Compared to the SP topology, TCT requires 25 additional wires for a $6 \times 6$ array. Considering the length of one wire as 2 feet, the total required wire length is 50 feet, and the cost of one wire is taken as $\$ 1$. Therefore, the total cost needed for the TCT configuration is $\$ 50$.

Similarly, the cost per unit is considered as $\$ 0.107$; then, the total units saved $=\$ 0.107 * 193=\$ 20.65$.

Payback time in a year $=\frac{50}{21}=2$ Years 5 months
A cost study shows that 25 additional TCT connections are needed to mitigate partial shading. These twenty-five extra connections cost $\$ 50$ more than SP. Within 2 years and 5 months, a solar PV array with a 25 -year lifespan returns more power than an SP array with long narrow shading, and Table 14 shows the payback times of conventional and hybrid configurations compared to TCT.

Table 14. Payback time of TCT Configuration compared to other topologies

| Shading <br> Pattern | Topology | \% Power <br> Enhancement | Payback Time |
| :---: | :---: | :---: | :---: |
|  | SP | 6.3 | 2 years 5 <br> months |
|  | BL | 6 | 1 year 3 months |
|  | LN | HC | 5.6 |
|  |  |  |  |
|  | LD | 6.5 | 5 Months |
|  | TrCT | 4.3 | 4 Months |
|  | SPTCT | 4.4 | 1 year 4 months |
|  | BLTCT | 3.1 | 11 Months |
|  | HCTCT | 4.4 | 1 Year |

## 5. CONCLUSIONS

This article delved into the assessment of passive techniques for mitigating the effects of partial shading in various shading scenarios. The subsequent analysis revealed the following observations:

In the DIA shading condition, the TCT configuration attains the highest power output of 2490 W . It also exhibits the lowest power loss due to mismatch at $1.88 \%$, alongside optimal Fillfactor and efficiency values of 0.69 and 13.84 , respectively.
For SN, SW, and LW shading schemes, the differences in maximum power among all topologies are small, and TCT generates maximum power of $2296 \mathrm{~W}, 1828 \mathrm{~W}$, and 1687 W , respectively.

In the LN shading condition, the TCT configuration achieves a peak power output of 2224 W , with a lowest mismatch power loss of $9.89 \%$. Additionally, it attains an optimal Fill-factor of 0.64 and an efficiency of $12.8 \%$.
In conclusion, optimizing a photovoltaic (PV) array's maximum power potential can be achieved through reducing mismatch power loss or the number of series interconnections between individual modules. This study contributes to the design of PV module interconnections in densely populated areas by utilizing data related to peak power locations and shading factors. Additionally, optimal fill factor results from distributing shade uniformly across the entire string, as opposed to concentrating it in a singular spot. Ultimately, both the arrangement of the photovoltaic array and the manner in which shading is patterned and positioned significantly influence its overall effectiveness. When considering all the configurations, TCT exhibits the most favorable performance across a majority of shading conditions. Despite its higher initial expense due to increased interconnections among panels, this cost is recuperated in two years and five months.
